## 1. Scope of the analysis

The objective of this work is to model the storage of electric energy produced but not used by the facility for longer-term utilization with the following technologies:

- Li-ion/Lithium Iron Phosphate (LiFePO<sub>4</sub>),
- VRFB,
- NaS,
- Electrolysis (PEM).

Within the framework of the analysis, we developed two models for each technology with different technical parameters, using empirical consumption data provided by ELI-HU Non-Profit Ltd.

The models present the balance of energy production, storage and consumption as time-series and cumulative data, as well as the financial means required to build and operate the storage capacities and the savings generated by the operation of the new infrastructure in monthly, quarterly and yearly intervals, as well as cumulatively for a 5-year period.

## 2. Notes on modelling

Table 1. Summary of the modelling methodology

| Description   | Features  | Source  |
|---|---|---------|
| Consumption data  | Data provided by ELI-HU Non-Profit Ltd.   | -       |
| Energy production data of the solar power plants ("Floating, Tracker, East-West 400V, Large Carport, East-West 800V") | Modelled value based on NASA's database, taking into account data provided by ELI-HU Non-Profit Ltd.  | -       |
| Evaluation of data  | Monthly, quarterly, yearly, five-year intervals   | -       |
| Evaluation of modelling   | Based on hourly data  | -       |
| Calculation of the rated capacities of battery energy storage systems   | Based on the average of annual data: 1100 MW  | [1]     |
| Calculation of the storage capacities of battery energy storage systems   | <u>Scenario 1</u> : short discharge time of up to 2 hours:<br>This corresponds to 2 hours of rated operation at rated output power, which means that in principle the battery can be fully charged and discharged in 2 hours.<br><u>Scenario 2</u> : long discharge time of up to 6 hours:<br>This corresponds to 6 hours of rated operation at rated output power, which means that in principle the battery can be fully charged and discharged in 6 hours.   | [1]     |
| Calculation of the rated power of PEM   | Based on the commercially available container technology<br><u>Scenario 1</u> : lower power ("MC250"), which takes into account the consumption data: 1.25 MW.<br><u>Scenario 2</u> : higher power ("MC500"), which takes into account the consumption data: 2.5 MW.  | [2–4]   |
| Average electricity demand considered for H <sub>2</sub> generation (kWh/kg)  | 50.4  | [2–4]   |
| Electric to electric efficiency considered  | Li-ion: 87%, LiFePO <sub>4</sub> : 88%, NaS: 73%, VRFB: 70%<br>- For LiFePO <sub>4</sub> , Li-ion and VRFB based technologies, the electric to electric efficiency takes into account cumulatively the average RTE loss of the battery module or cell, the "Balance of Systems" (BOS) loss of the system accessories, and the average effect of auxiliary systems (e.g. cooling, heating).<br>- For NaS based technology, the electric to electric efficiency takes into account cumulatively the average RTE loss of the battery module or cell, the average Balance of Systems (BOS) loss of the system accessories, the average effect of auxiliary systems and heat losses. | [5–17]  |
| Electricity tariff considered, with RHD charge (HUF/kWh)  | 97.13   | -       |
| H <sub>2</sub> sales price considered (kg/USD; kg/HUF)  | 4.5; 1665   | [18]    |
| Was technical depreciation due to battery use considered for the relevant technologies?                               | Yes   | [19]    |
| Was the H <sub>2</sub> loss considered for storage?   | Yes, mean value: 5.075%   | [20–22] |
| Capital expenses  | Validated by Hungarian and international market players   | -       |

### 3. Evaluation of the modelling results

#### 3.1. LiFePO4, Scenario 1

Table 1. LiFePO4 model-based energy efficiency analysis, Scenario 1

| Time interval | Facility's total (grid) consumption, without PV system and energy storage (MWh) | Facility's total (grid) consumption, with PV system, without energy storage (MWh) | Facility's total consumption, with PV system, with LiFePO4 energy storage (MWh) | Solar energy production data (MWh) | Solar energy overproduction data, without energy storage (MWh) | Solar energy overproduction data, with LiFePO4 energy storage (MWh) | Discharge demand of the LiFePO4 battery, with regard to the electricity to electricity efficiency (MWh) | Battery cycle count |

## **4. Evaluation of the modelling results**

### **4.1. Changes in total grid consumption and solar energy production with the studied technologies in the given scenarios**

This subsection presents the total grid consumption and the changes in solar generation data for the studied technologies and scenarios (Tables 28-29 and Figures 97-100). It has been found that over a period of one year and five years, the total (grid) consumption of the facility without a PV system and an energy storage solution would equal 9,577 MWh and 47,885 MWh, respectively. This can be reduced to 55% with a PV system without an energy storage system, as well as to 48-50% with an energy storage solution (Scenario 1) or to 40-41% (Scenario 2). The results on the energy production of solar power plants have shown that over a period of one year and five years, PV plants produce 7,503 MWh and 37 514 MWh of electricity respectively. Without an energy storage solution, the facility would be unable to use 42% of this energy for own consumption. With the studied electrochemical energy storage solutions this value could be reduced to 31-33% (Scenario 1) or 15-20% (Scenario 2) over a year and to 31-36% (Scenario 1) or 15-22% (Scenario 2) over a period of five years. With H<sub>2</sub> generation, only 13% (Scenario 1) and 2% (Scenario 2) of the electricity generated by the PV system would not be directly consumed by the facility over each time horizon.

Table 28. Changes in the total grid consumption and in solar energy production data with the studied technologies and scenarios, over a period of 1 year and 5 years, respectively

| Time interval | Initial data  |  | Scenario 1  |  |   |  |  | Scenario 2  |  |   |  |  |

## **4.2. Changes in total grid consumption costs and cost savings with the studied technologies in the given scenarios**

This subsection presents the total grid consumption costs and the changes in cost savings with the studied technologies and scenarios (Table 30 and Figures 101-102). It has been found that over a 5-year period, the cost of the facility's total (grid) consumption without a PV system and an energy storage solution would equal HUF 4,651.1 million, which could be reduced to HUF 2,544.3 million with a PV system without an energy storage solution. With energy storage solutions, this amount could be reduced to: HUF 2,340.5 million with a LiFePO<sub>4</sub> based energy storage system; to HUF 2,340.6 with a Li-ion based energy storage system; to HUF 2,250.4 million with a VRFB based energy storage system (Scenario 1) and to: HUF 1,890.2 million with a LiFePO<sub>4</sub> based energy storage system; to HUF 1,890.2 with a Li-ion based energy storage system; to HUF 1,838.7 million with a NaS based energy storage system; and to 1,838.7 million with a VRFB based energy storage system (Scenario 2).

The cost savings achievable by the facility with the studied energy storage technologies and scenarios are the following:

- Over 5 years, the cost savings on the facility's total (grid) consumption with a PV system but without an energy storage solution would equal HUF 2,107 million. This amount could be reduced to HUF 2,311 million with LiFePO<sub>4</sub>, to HUF 2,310 million with Li-ion, to HUF 2,401 million with VRFB batteries (Scenario 1), as well as to HUF 2,761 million with LiFePO<sub>4</sub>, to HUF 2,761 million with Li-ion, to HUF 2,812 million with NaS, and to HUF 2,812 million with VRFB batteries (Scenario 2).

### **4.3. Energy and cost savings achievable with the studied technologies in the given scenarios**

This subsection presents the energy and cost savings achievable with the studied technologies and scenarios (Tables 31-32 and Figures 103-104). It has been found that the discharge rate of energy storage technologies differs in the different scenarios, not only due to the different electric to electric efficiency, but also due to the level of technical depreciation. In this context, it should be noted that in the VRFB and NaS energy storage technologies, the condition of the energy storage devices does not depend on the cycle count, so practically they are not subject to technical depreciation. However, in Li-based technologies, the number of cycles has a negative impact on the energy storage capacity, which is 0.003% per cycle. Based on these results, the discharge demand of the energy storage technologies over 5 years is the following: 2,098 MWh for LiFePO<sub>4</sub>, 2,097 MWh for Li-ion, 3,026 MWh for VRFB (Scenario 1), and 6,735 MWh for LiFePO<sub>4</sub>, 6,734 MWh for Li-ion, 7,265 MWh for NaS and 7,264 MWh for VRFB (Scenario 2). In addition, the amount of solar energy used for H<sub>2</sub> production, taking into account the solar energy overproduction data, equals 1,1051 MWh (Scenario 1) and 15,206 MWh (Scenario 2). Most of the overproduction of solar energy by the PV system can be handled with the help of H<sub>2</sub> generation. The cost savings are as follows:

- Scenario 1
  - LiFePO<sub>4</sub>: HUF 203.7 million
  - Li-ion: HUF 203.7 million
  - VRFB: HUF 293.9 million
  - H<sub>2</sub>: HUF 346.5 million
- Scenario 2
  - LiFePO<sub>4</sub>: HUF 654.1 million
  - Li-ion: HUF 654.1 million
  - NaS: HUF 705.6 million
  - VRFB: HUF 705.6 million
  - H<sub>2</sub>: HUF 476.8 million

#### **4.4. Capital expenses and maintenance costs of the studied technologies in the given scenarios**

This subsection presents the capital expenses and maintenance costs of the studied technologies studied for each scenario (Tables 33-35 and Figures 105-106).

It has been found that among the different battery technologies, the NaS technology has the lowest capital expenses (200-300 EUR/kWh), the lowest capital expenses for the complete system (300-400 EUR/kWh) and the lowest annual maintenance costs, which equal 1-2% of the battery price. This system can be used for larger energy storage capacities. Therefore, in Scenario 2, the capital expenses of the NaS battery are estimated to be EUR 1,320-1,980 thousand, the capital expenses of the complete system are expected to equal EUR 1,980-2,640 thousand, and the annual maintenance costs are estimated to total EUR 13-40 thousand. For long-term energy storage, the NaS technology has been found to show the most favourable values in terms of capital expenses and maintenance costs alike. Today, even the initial capital expenses of NaS batteries are lower than those of LiFePO<sub>4</sub> and Li-ion batteries, and the maintenance costs are also lower than those of the other technologies. It is worth noting that VRFB batteries are the most expensive, both in terms of capital expenses and maintenance costs. For safety, operational and maintenance reasons, the LiFePO<sub>4</sub> technology is preferable to Li-ion technology for short-term energy storage (Scenario 1). In this respect it is worth noting that LiFePO<sub>4</sub> batteries have a more stable chemical structure and are therefore less prone to fires than Li-ion batteries.

The average capital expenses of equipment required for the investigated liquid H<sub>2</sub> generation technology is estimated to be EUR 2.2 million (Scenario 1) and EUR 4.4 million (Scenario 2); the total capital expenses are estimated to be EUR 3.5 million (Scenario 1) and EUR 7 million (Scenario 2); and the annual maintenance costs are expected to equal EUR 0.1-0.17 million (Scenario 1) and EUR 0.21-0.35 million (Scenario 2). This also means that this option is the most expensive of all the technologies we studied.

Table 33. Capital expenses and maintenance costs of the studied battery technologies per 1 kWh in the given scenarios

| <b>Battery type</b> | <b>Capital expenses of the battery (EUR/kWh)</b> | <b>Capital expenses of the complete system (EUR/kWh)</b> | <b>Annual maintenance costs</b>  |
|---------------------|--|--|----------------------------------|

\*For LiFePO<sub>4</sub>, Li-ion and VRFB based technologies, the electric to electric efficiency takes into account the average RTE loss of the battery module or cell, the "Balance of Systems" (BOS) loss of the system accessories, and the average effect of auxiliary systems (e.g. cooling, heating).

\*\* For NaS based technology, the electric to electric efficiency takes into account the average RTE loss of the battery module or cell, the average Balance of Systems (BOS) loss of the system accessories, the average effect of auxiliary systems and heat losses.

\*\*\* The average values used in the table have been validated by Hungarian and international market players, the prices in the table reflect European and Hungarian averages, more precise values can be established on the basis of specific quotations.

Table 37. Summary of the battery modelling results for a concrete LiFePO4 quotation

| Cost savings with the battery (EUR thousand)   | 509   | 1635   | 509                   | 1635                  | 735                 | 1764                | -                  | 1764               |

\*For LiFePO4, Li-ion and VRFB based technologies, the electric to electric efficiency takes into account the average RTE loss of the battery module or cell, the "Balance of Systems" (BOS) loss of the system accessories, and the average effect of auxiliary systems (e.g. cooling, heating).

\*\* For NaS based technology, the electric to electric efficiency takes into account the average RTE loss of the battery module or cell, the average Balance of Systems (BOS) loss of the system accessories, the average effect of auxiliary systems and heat losses.

\*\*\* The average values used in the table have been validated by Hungarian and international market players, the prices in the table reflect European and Hungarian averages, more precise characteristics can be established on the basis of specific quotations.

\*\*\*\*LiFePO4 values are based on specific quotations

Tables 36 to 37 show that a concrete purchasing decision can only be taken when concrete market offers are available. This is because there are significant differences between the average capital expenses and maintenance costs in Europe and in Hungary (Table 36) (Table 37).

Based on the results presented in Table 36, the NaS technology is recommended for long-term energy storage needs. For short-term energy storage, the VRFB technology is preferable to lithium-based technologies.

Taking into account the results in Table 37, which includes a specific quotation, we recommend the use of either the LiFePO<sub>4</sub> or the NAS technologies.
